

## Dialogue Design

# Logical Input Devices

Physical Devices are mapped onto Logical Input Devices, which are divided into six different classes according to ISO/ANSI API standards

**/\*\* GKS, PHIGS, PHIGS+ \*\*/**

### Logical Input Classes

<b><u>LOCATOR</u></b>	Returns a position in World Coordinates.
<b>STROKE</b>	Returns a sequence of points in World Coordinates.
<b><u>VALUATOR</u></b>	Returns a real number.
<b>CHOICE</b>	Returns a selection (positive integer) from a set of alternatives.
<b><u>PICK</u></b>	Identifies a displayed and selected object (pick path).
<b>STRING</b>	Inputs a sequence of characters.

(old technology)

The diagram illustrates the relationship between physical input devices and their corresponding abstractions. It features two large ovals: a light blue one on the left labeled "REAL DEVICES" and a light pink one on the right labeled "ABSTRACTIONS". A central white box with a blue border contains the title "Typical Physical Input Devices and mapping" and six rows of mappings. Each row consists of a device name, a series of yellow arrowheads pointing right, and an abstraction name. The mappings are as follows:

Real Device	Abstraction
Crosshairs	<u>LOCATOR</u>
Tablet (Mesa Digitalizadora)	<u>STROKE</u>
Potenciometer	<u>VALUATOR</u>
Button Box	<u>CHOICE</u>
Light pen	<u>PICK</u>
Keyboard	<u>STRING</u>

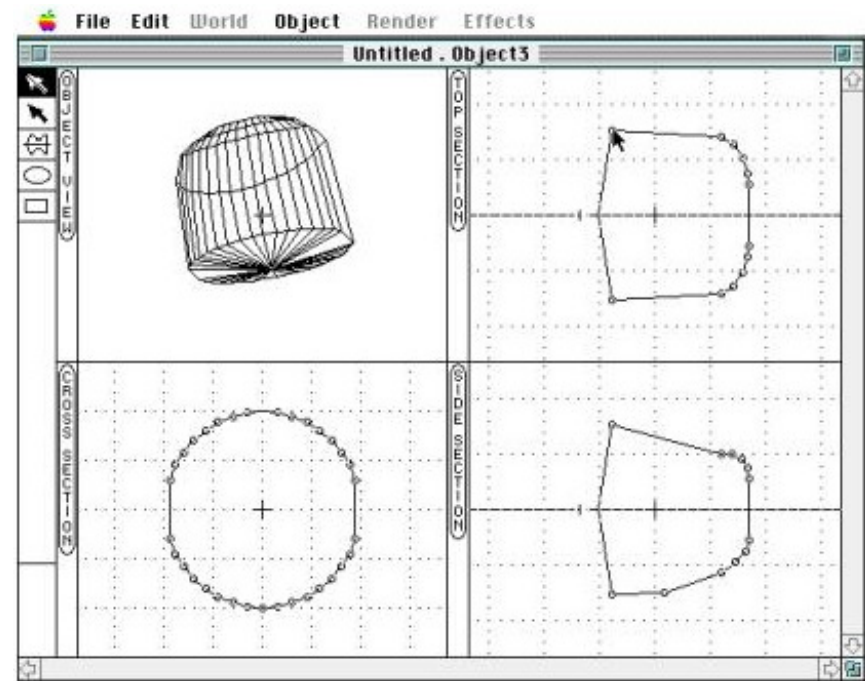

Note:  
- The keyboard can emulate any input class (very poor UI!);

- The keyboard can emulate any input class (very poor UI!);
- The underlined names are still used nowadays.

PICK

LOCATOR

Initial screen image

PICK  
(with visual feedback)

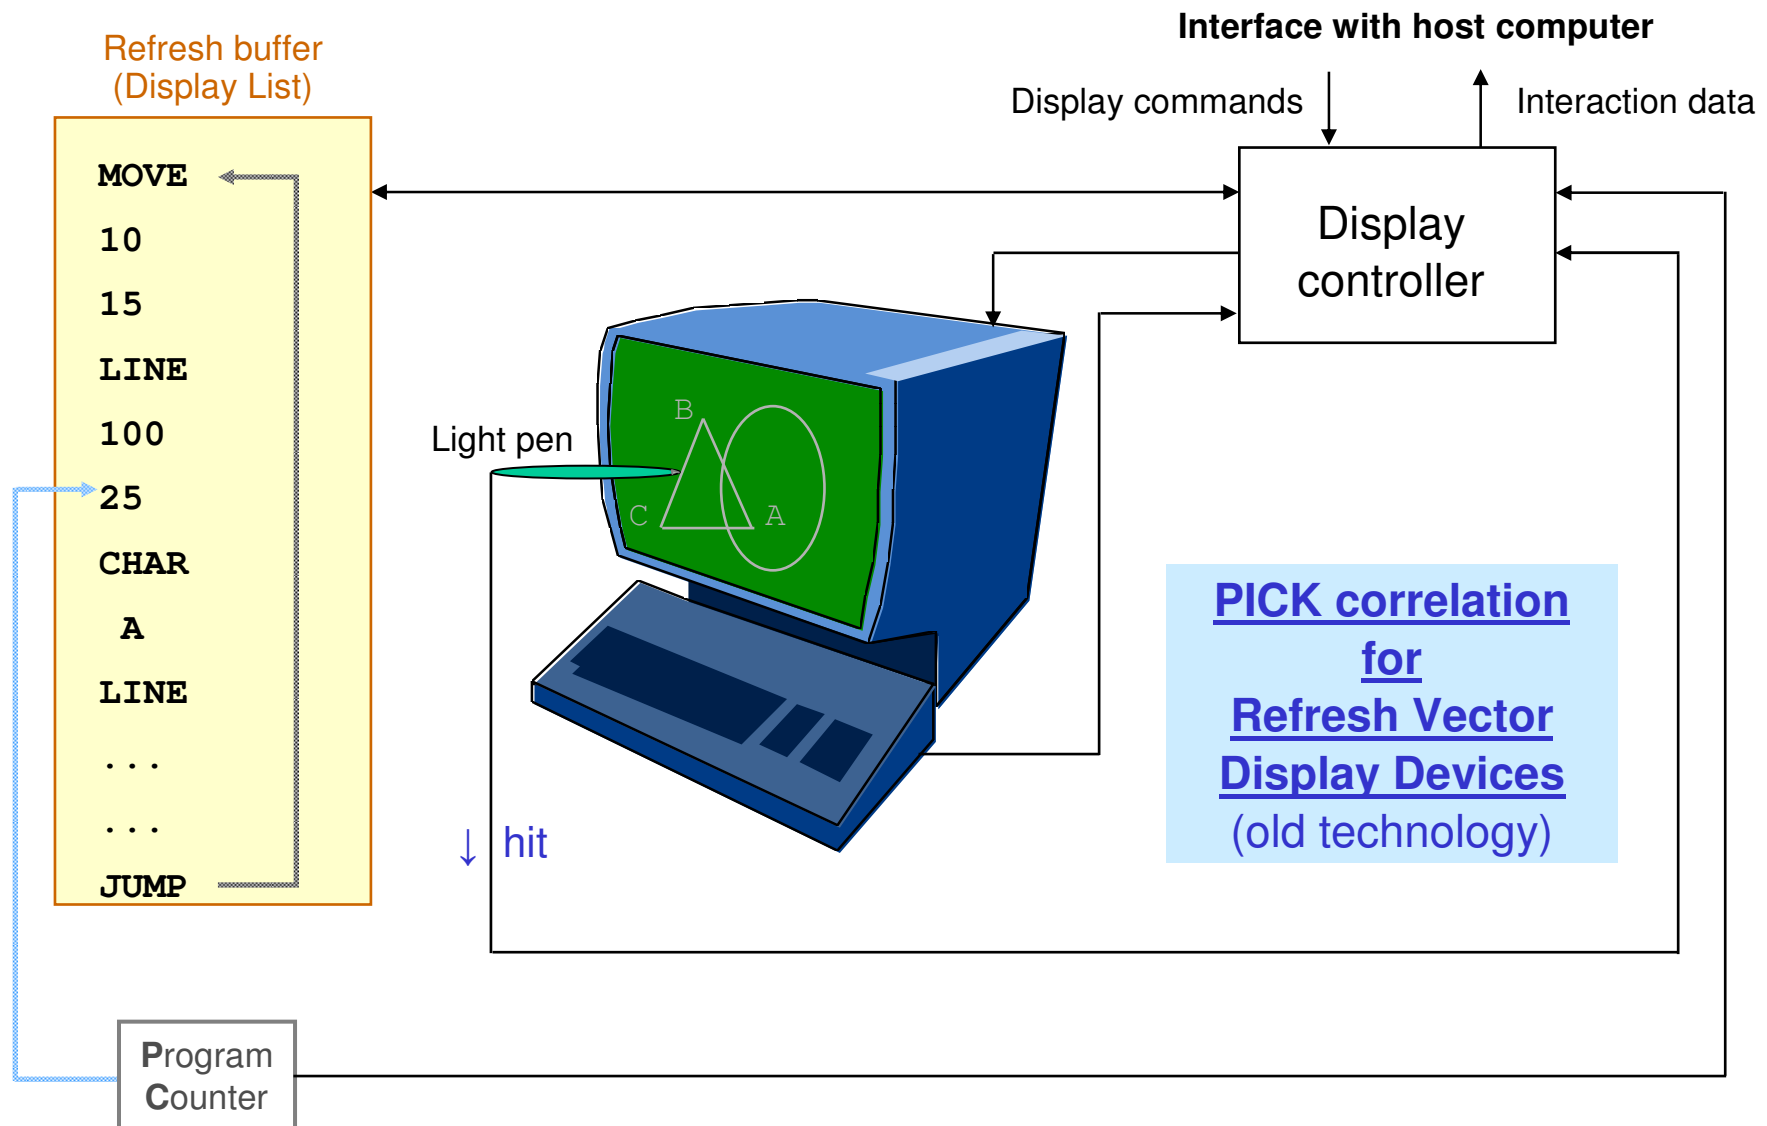

CHOICE (menu item)

followed by

VALUATOR (rotation)

Final screen image

When a hit is detected by the Display Controller, the Program Counter indicates the location of the selected object in the code

# PICK CORRELATION TRAVERSAL FOR RASTER GRAPHICS

## (1) ANALYTICAL HIT DETECTION

Algebraic equations are used to determine whether the DC (device coordinate) primitive lies sufficiently close to the 2D DC locator measure.

Algorithms are needed for:

- Computing the distance from the cursor position to each line segment.
- Determining if the cursor position lies inside a polygon [see the even-odd fill area algorithm].
- Comparing the locator position to the rectangular screen extent for nongeometric text.

Optimization/approximation can be done by using **Screen Extents**:

Problems with the selection of the *star* ?

A possible solution: priority lists based on the object size  
(*star* → *moon* → *triangle*)

# PICK CORRELATION TRAVERSAL FOR RASTER GRAPHICS

## (2) HIT DETECTION VIA CLIPPING

Hardware clipping devices and/or optimized software clipping utilities allow the application to determine whether any part of a primitive's image lies inside a 2D integer clip rectangle (a small square surrounding the cursor position called **PICK WINDOW**) without having actually to draw the primitive on the screen for that purpose.

One of the following methods can be used :

- Drawing into an offscreen pixmap (buffer) and checking if any pixels are changed.
- Hit detection returned by the clipper.

A stack of names (push&pop procedures) is used and the current name is read every time a hit is detected. Then we can easily identify the associated set of primitives responsible for the hit.

To be compared with the Light Pen technique (see the PICK applet example)
